19. Consider a tank which initially holds $V_{0}$ liter of brine that contains a lb of salt. Another brine solution, containing b lb of salt per liter is poured into the tank at the rate of $e L / \mathrm{min}$. The problem is to find the amount of salt in the tank at any time $t$.

Let Q denote the amount of salt in the tank at any time. The time rate of change of $\mathrm{Q}, \frac{d Q}{d t}$, equals the rate at which salt enters the tank at the rate at which salt leaves the tank. Salt enters the tank at the rate of be $\mathrm{lb} / \mathrm{min}$.

To determine the rate at which salt leaves the tank, we first calculate the volume of brine in the tank at any time t , which is the initial volume $V_{0}$ plus the volume of brine added et minus the volume of brine removed ft .

Thus, the volume of brine at any time is

$$
V_{0}+e t-f t
$$

The concentration of salt in the tank at any time is $Q /\left(V_{0}+e t-f t\right)$, from which it follows that salt leaves the tank at the rate of $f\left(\frac{Q}{V_{0}+e t-f t}\right) \mathrm{lb} / \mathrm{min}$. Thus, $\frac{d Q}{d t}=b e-f\left(\frac{Q}{V_{0}+e t-f t}\right) Q=b e$

A tank initially holds 100 L of a brine solution containing 20 lb of salt. At $\mathrm{t}=0$, fresh water is poured into the tank at the rate of $5 \mathrm{~L} / \mathrm{min}$, while the well-stirred mixture leaves the tank at the same rate. Then the amount of salt in the tank after 20 min .
